

Ecopath with Ecosim technical papers: Sharing external spatial-temporal data

EwE development team

Ecopath Research and Development Consortium
Ecopath International Initiative, University of British Columbia

Abstract

With the introduction of the Spatial Temporal Data Framework (e.g., *framework*), Ecospace, the spatial-temporal module of the EwE modelling approach, gained the possibility to vary its input maps over time via time series of maps that are available outside a EwE model. The framework is described in detail in Steenbeek (2012) and Steenbeek et al (2013). For the purpose of this document, the structure of the framework, and the terms ‘dataset’, ‘converter’, and ‘adapter’, are presumed to be familiar and can be obtained from Steenbeek (2012) and Steenbeek et al (2013).

Because EwE modellers share models, external data connections need to be shared as well. Facilities to export and share external data configuration between software users was added to the development version of EwE 6.5, which allows models to retain their data accessibility across computers, but has also complicated the process of configuring Ecospace scenarios to a point that can become rather confusing.

This document describes the structure of sharing external data, and provides recommendations how to improve this structure.

External data

In the context of the Spatial Temporal Data Framework, the term ‘external data’ refers to any data not embedded within a EwE model database, and is thus external to the EwE model.

By its design, the framework allows external data connections to any source: local or remote files, web services, THREDDS and OpenDap connections, and running models are among possibilities. To date, only file based access has been implemented for the framework.
